Phosphodiesterases As Drug Targets Handbook

Introduction. Cyclic nucleotide phosphodiesterases (PDEs) are promising targets for pharmacological intervention. Multiple PDE genes, isoform diversity, selective expression and compartmentation of the isoforms, and an array of conformations of PDE proteins are properties that challenge development of drugs that selectively target this class of enzymes.

PDEs as drug targets As selected PDE family members are critical regulators of cyclic AMP signaling, they make terrific targets for designing new medicines. For example, PDE4 inhibitors such as Otezla ® (apremilast) and Daxas ® (roflumilast) exert their effects by reducing cyclic AMP breakdown and enhancing the cyclic AMP signal.

A phosphodiesterase type 4 inhibitor, commonly referred to as a PDE4 inhibitor, is a drug used to block the degradative action of phosphodiesterase 4 (PDE4) on cyclic adenosine monophosphate (cAMP). It is a member of the larger family of PDE inhibitors. The PDE4 family of enzymes are the most prevalent PDE in immune cells.
